

TestNG Integration & Setup | @Test Automation

16 August 2024 11:08

TestNG --> Test New Generation --> Java based unit testing tool.

Unit testing --> developers will unit test the methods created by them by passing different parameters they will verify whether the methods returning value or not.

Advantages:

- 1) We will manage Test cases & Test Suites using TestNG
- 2) Grouping of test cases
- 3) Prioritize
- 4) Parameterization - we can pass runtime parameters at runtime like (we will pass browser name at runtime)
- 5) Parallel Testing
- 6) Reports

TestNG Configuration

- 1) Install testng in eclipse
- 2) Add testng library to build path/ add testng dependency in pom.xml

Annotations

@Test -- replacement for main method.

1. TestNG execute methods based on alphabetical order
2. @Test(priority=num) controls the order of execution.
- 3) Once you provide priority to the test methods, then order of the methods is not considered.
- 4) Priorities can be random numbers (no need to have consecutive numbers)
- 5) If you don't provide priority then default value is zero(0).
- 6) If the priorities are same then again execute methods in same alphabetical order.
- 7) Negative values are allowed in priority
- 8) TestNG will only execute test method only if they are having @Test annotation

Execute testcases using testng xml file

Test xml file

- 1) generate automatically
- 2) Manually

Test Suite -----> Test cases -----> test steps

XML file -----> classes -----> Test methods

What is the necessity of creating xml file manually even though if we can create it automatically.

But later on if we want to add grouping, listeners, parameters we can do it through by creating it as

manually.

We will get only basic tags like suite classes and test in case of automatic creation.

2 things we achieved through xml

- 1)executed group of test cases as a 1 suite
- 2)We can generate testng reports (default)
