

Handling Broken Links, SVG Elements, Shadow DOM

08 August 2024 10:26

Broken Links:

Sometimes when you click on the link we will not get target page. That page doesn't have a resource in the server. Page not found resource not available, 404 page not found.

Before hitting the link it should have href attribute then only we can check whether it is broken link or not.

- 1) Link href="https://xyz.com"
- 2) href="https://xyz.com" --- server --- status code
- 3) Status code ≥ 400 broken link
- 4) Status code < 400 not a broken link

SHADOW DOM

Web Technology where developers keep one dom inside another dom to reduce load. If we keep all the elements in single dom it will take more time to

DOM -document object model

DOM will be generated during runtime that is when we try to load any URL on the Web.

Document(WebPage) ----> Shadow Host -----> Shadow Root -----> Element

This is the only place where xpath doesn't work to locate WebElement.

By using CSS Selector only we can find shadow DOM element.

Which ever is holding the shadow root that is called shadow host.

Shadow Element.

Nested Shadow Element.

Multi Nested Shadow Element.

```
//This Element is inside single shadow DOM.  
String cssSelectorForHost1 = "book-app[apptitle='BOOKS']";  
Thread.sleep(1000);  
SearchContext shadow = driver.findElement(By.cssSelector("book-app[apptitle='BOOKS']")).getShadowRoot();  
Thread.sleep(1000);  
shadow.findElement(By.cssSelector("#input"));
```

Practice:

<https://dev.automationtesting.in/shadow-dom>

SVG Elements

These also can't be located using SVG elements.

By using name() method we can access SVG Elements.

```
//a[normalize-space()='']/*[name()='svg']  
//a[@class='oxd-main-menu-item active']/*[name()='svg']  
//a[normalize-space()='']/*[name()='svg']
```
