Even though if the first method fails testng tries to execute remaining methods and those methods also will fail. Its a completely waste of time and effort but we don't want to happen that.

When ever a method fails I want to skip the dependent methods in order to save time and effort

```
dependsOnMethods= {"dependency method1", "dependency method1", .....}
```

Grouping

```
Class1    - m1 m2 m3
Class2    - m4, m5, m6
Class3    - m7, m8, m9
Class4    -
```

In grouping we will group the methods not the classes

Will group methods into multiple categories

Most of the time we will group them based on type

Sanity -- basic functionality test login signup - if these fail we cannot proceed further

Regression --

Functional - all the tests sanity regression

The grouping will start before starting automating the test cases or during manual testing time itself
We will update one flag and categorize whether it is sanity regression or functional

Grouping concept will only possible through xml file

```
loginByFacebook --->sanity
Loginbyemail     ---->sanity
Loginbytwitter   ----->sanity
```

```
Signupbyfacebook - regression
Signupbytwitter  - regression
Signupbyemail    - regression
```

Payment in rupees - sanity, regression(functionl)

Payment in dollars - sanity, regression (functional)

- 1) All sanity tests
- 2) All regression tests
- 3) All sanity but not regression
- 4) All regression but not sanity
- 5) All methods which are belongs to both sanity & regression
